WardWatch

A Responsive Civic-Tech Framework for Community Infrastructure Management

By Asmita Guha, Reg No.: 230911112, IT-D, Roll No.: 19

1. Introduction

WardWatch is a cross-platform application that helps local residents communicate with their municipal representatives and is driven by data. Residents are able to report problems related to their infrastructure like road issues, cleanliness, and electricity problems. Residents are also able to see what is being done to resolve the issues with the help of real-time tracking. WardWatch enables the local authorities to have a data-driven approach to solve community issues that are regularly reported. This is done with the power of modern web tools and persistent cloud storage.

2. Problem Statement

Traditional methods of civic reporting and complaints about infrastructure issues posted on social media are not tangible, unified, or systematic. This makes the problems fall into a feedback black hole. This goes on for a long time, and the local authorities don't have an organized system to see what issues to solve. This is a perfect example of a system that lacks persistence and verifiable systems to track the life cycle of problems that were reported until the problems are resolved.

3. Objectives

- **Platform Versatility:** To develop a responsive web-first application using **Flutter** that ensures accessibility across desktops, tablets, and smartphones.
- **Data Integrity & Persistence:** To use **Supabase (PostgreSQL)** or **Firebase (Firestore)** to store data at the backend for secure, long-term data storage.
- **Operational Transparency:** To establish a transparent role-based workflow (Resident vs. Admin) that tracks the status of reports through various stages: *Submitted, Acknowledged, In-Progress,* and *Resolved*.
- **Evidence-Based Governance:** To provide a multimedia-supported reporting tool that allows users to upload photographic evidence, ensuring higher quality and accuracy in reported data.

4. Technical Specifications

The tech stack is selected for its scalability, industry-standard security, and high performance-to-cost ratio:

Layer	Primary Technology	Description
Frontend UI/UX	**Flutter (Dart)**	Leverages a single codebase for a responsive, high-performance web experience.
Backend-as-a-Service	**Supabase / Firebase**	**Supabase (Postgres):** High-integrity relational mapping for complex queries. **Firebase (NoSQL):** Low-latency document synchronization.
Persistent Storage	**S3-Compatible Storage**	Cloud-based hosting for multimedia assets (Supabase Buckets or Firebase Storage).
Authentication	**OAuth 2.0 / JWT**	Secure, industry-standard user identity management and role-based access control.
CI/CD & Hosting	**Vercel / Firebase Hosting**	Automated deployment pipelines for high-availability web hosting.

5. Future Scope & Research Potential

The objective of WardWatch's architectural design is to provide a basis for the consideration of scalable design principles for urban computing and civic-tech research perspectives, the researching of which could develop into wider programs of activity described as 'urban computing'. The possibilities for this direction may be as follows:

- **Empirical Case Studies:** A deployment may be made of the platform for localised pilot case studies in municipalities within specific wards where longitudinal data can

be gathered about resident engagement and the efficacy of digital feedback devices to assist with local governance.

- **Performance Analytics:** The aggregate data collected through the system allows for comparative analyses of municipal response times; such research would be able to support the discussion around and support the impact of crowdsourced data on the efficiency of municipalities, and would encourage efforts to present this research at international forums such as IEEE Smart Cities.
- **Computer Vision Integration:** To enhance the validating process, future iterations of WardWatch may explore the possible benefits of integrating deep learning (CNN) models into the validation process where the system would (1) provide categorisation of issues based on user-submitted images and (2) allow for a preliminary assessment of issues with the level of severity ascribed to them; this work will reduce the number of manual administrative triage activities required by providing an easier way to assess issues based on image submissions.
- **Data-Driven Governance Models:** The structured datasets produced as a result of using the platform may, with time, become an initial working foundation for the prediction of maintenance of critical infrastructure by assisting municipalities in identifying infrastructure at risk of failure before critical failures occur.

6. Future Expansion

- **GIS Integration:** Google Maps APIs embedded into the application providing a “heatmap,” allowing authorities to see clusters of high-needs areas.
- **Multilingual Support:** Expanding UI to include local languages to accommodate all residents in the ward, creating an inclusive environment.
- **Gamification Engine:** Implementing a Community Contributor Leaderboard so that residents are encouraged to report issues and to verify others’ work, resulting in a sense of community pride.
- **Automated Notifications:** Integrated with Twilio or SendGrid to send automated SMS/Email notifications to residents as their reported problems progress through the resolution pipeline.
